# 2024 AMC 12B Problem 22

Let $\triangle ABC$ be a triangle with integer side lengths and the property that $\angle B = 2\angle A$. What is the least possible perimeter of such a triangle?

(A) 13   **(B)** 14   **(C)** 15   **(D)** 16   **(E)** 17

Solution

Key Word Law of Sines, Law of Cosines, Trigonometric Identities, Property of Triangle

The fact that a, b and c are integers may be utilized.

According to the Law of Sines, the following equation is true.

$$\frac{b}{\sin 2\alpha} = \frac{a}{\sin \alpha}$$
$$\frac{b}{2 \sin \alpha \cos \alpha} = \frac{a}{\sin \alpha}$$
$$\cos \alpha = \frac{b}{2a} \quad (\because 0° < \alpha < 90°)$$

Moreover, using the Law of Cosines, an additional equation may be driven.

$$\cos \alpha = \frac{b^2 + c^2 - a^2}{2bc}$$

Substitute $\cos \alpha$ to $\cos \alpha = \frac{b}{2a}$.

$$\frac{b^2 + c^2 - a^2}{2bc} = \frac{b}{2a}$$
$$2a(b^2 + c^2 - a^2) = 2b^2 c$$
$$2ab^2 + 2ac^2 - 2a^3 = 2b^2 c$$
$$2b^2(a - c) + 2a(c^2 - a^2) = 0$$
$$2b^2(a - c) - 2a(a + c)(a - c) = 0$$
$$(a - c)(2b^2 - 2a(a + c)) = 0$$
$$(a - c)(2b^2 - 2a^2 - 2ac) = 0$$

Thus, $a - c = 0$ or $2b^2 - 2a^2 - 2ac = 0$ or both is true. However, when $a = c$, $\alpha = 45°$, which leads to non-integer length for at least one of the sides.

$$\therefore 2b^2 - 2a^2 - 2ac = 0$$
$$b^2 = a^2 + ac$$
$$b^2 = a(a + c)$$

Because the least possible perimeter of such a triangle must be found, the values for a, b and c could be substituted.

b	a	c	$Validity$	
1	1	0	No	
2	1	3	No	$(\because 3 = 2 + 1)$
2	2	0	No	
3	1	8	No	$(\because 8 > 3 + 1)$
3	3	0	No	
4	1	15	No	$(\because 15 > 4 + 1)$
4	2	6	No	$(\because 6 = 4 + 2)$
4	4	0	No	
5	1	24	No	$(\because 24 > 5 + 1)$
6	1	35	No	$(\because 35 > 6 + 1)$
6	2	16	No	$(\because 16 > 6 + 2)$
6	3	9	No	$(\because 9 = 6 + 3)$
6	4	5	Yes	

Therefore, the least perimeter is $6 + 4 + 5$, which is $\boxed{\text{(C) } 15}$. $\qquad\square$
Problem

In $\triangle ABC$, $\angle B = 40°$ and $AB + BC = 2AC$. K and M are the mid-points of AB and BC respectively, while L is a point on AC such that BL bisects $\angle ABC$. Find $\angle KLM$.

Solution

Key Word Angle Bisector Theorem

According to the question, $AC = a + c$. Moreover, using Angle Bisector Theorem, it is evident that $AL = (a + c) \cdot \frac{c}{a+c}$ and $LC = (a + c) \cdot \frac{a}{a+c}$.

Using the property of triangle, $(180 - 2\circ) + (180 - 2\bullet) = 180 - 40$ is true. Thereby, $\circ + \bullet = 110$. In another words, $\boxed{\angle KLM = 70°}$. $\qquad\square$
Problem

In $\triangle ABC$, $AB + BC = 2AC$ and $\angle A = \angle C + 90°$. Find $\cos B$.

Solution I

Key Word Law of Sines, Law of Cosines

A vertical line from A could be drawn.

$\cos(90° - 2\theta)$, or $\sin 2\theta$, is the value that is required to be computed. According to the diagram, it is evident that $\sin 2\theta = \frac{c}{a-x}$.

To compute the value of x, trigonometric identities may be utilized. $\tan 2\theta = \frac{2\tan\theta}{1-\tan^2\theta}$ is true.

The Law of Sines may provide additional information.

$$\frac{\frac{a+c}{2}}{\sin(90-2\theta)} = \frac{c}{\sin\theta} = \frac{a}{\sin(90+\theta)}$$

In another words,

$$\frac{c}{\sin\theta} = \frac{a}{\cos\theta}$$
$$\frac{c}{a} = \frac{\sin\theta}{\cos\theta}$$
$$\tan\theta = \frac{c}{a}$$

Because $\tan 2\theta = \frac{2\tan\theta}{1-\tan^2\theta}$, $\frac{c}{x} = \frac{2 \cdot \frac{c}{a}}{1-(\frac{c}{a})^2}$.

$$a - x = a - c \cdot \frac{1 - (\frac{c}{a})^2}{2 \cdot \frac{c}{a}}$$
$$= a - (1 - \frac{c^2}{a^2}) \cdot \frac{c}{2 \cdot \frac{c}{a}}$$
$$= a - (1 - \frac{c^2}{a^2}) \cdot \frac{a}{2}$$
$$= \frac{a}{2}\left(2 - \left(1 - \frac{c^2}{a^2}\right)\right)$$
$$= \frac{a}{2}\left(1 + \frac{c^2}{a^2}\right)$$
$$= \frac{a}{2}\left(\frac{a^2 + c^2}{a^2}\right)$$
$$= \frac{a^2 + c^2}{2a}$$

Therefore, the value of $\sin 2\theta = \frac{c}{\frac{a^2+c^2}{2a}} = \frac{2ac}{a^2+c^2}$.

The Law of Cosines may provide supplementary information.

$$\cos\theta = \frac{a^2 + (\frac{a+c}{2})^2 - c^2}{2 \cdot a \cdot \frac{a+c}{2}}$$

$$\cos(90+\theta) = \frac{c^2 + (\frac{a+c}{2})^2 - a^2}{2 \cdot c \cdot \frac{a+c}{2}} = -\sin\theta$$

Using the fact $\tan\theta = \frac{c}{a}$ again, the following equations may be written.

$$\frac{c}{a} = \frac{\frac{a^2-(\frac{a+c}{2})^2-c^2}{2\cdot c \cdot \frac{a+c}{2}}}{\frac{a^2+(\frac{a+c}{2})^2-c^2}{2\cdot a \cdot \frac{a+c}{2}}}$$

$$= \frac{\frac{a^2-(\frac{a+c}{2})^2-c^2}{c}}{\frac{a^2+(\frac{a+c}{2})^2-c^2}{a}}$$

$$\frac{c^2}{a^2} = \frac{a^2 - c^2 - (\frac{a+c}{2})^2}{a^2 - c^2 + (\frac{a+c}{2})^2}$$

$$c^2\left(a^2 - c^2 + (\frac{a+c}{2})^2\right) = a^2\left(a^2 - c^2 - (\frac{a+c}{2})^2\right)$$

$$a^2c^2 - c^4 + \frac{c^2}{4}(a+c)^2 = a^4 - a^2c^2 - \frac{a^2}{4}(a+c)^2$$

$$c^2(a^2 - c^2) + \frac{c^2}{4}(a+c)^2 = a^2(a^2 - c^2) - \frac{a^2}{4}(a+c)^2$$

$$c^2(a - c) + \frac{c^2}{4}(a+c) = a^2(a - c) - \frac{a^2}{4}(a+c)$$

$$\frac{c^2}{4}(a+c) + \frac{a^2}{4}(a+c) = a^2(a - c) - c^2(a - c)$$

$$(a+c)(\frac{c^2}{4} + \frac{a^2}{4}) = (a - c)(a^2 - c^2)$$

$$(\frac{c^2}{4} + \frac{a^2}{4}) = (a - c)(a - c)$$

$$c^2 + a^2 = 4a^2 - 8ac + 4c^2$$

$$3a^2 + 3c^2 = 8ac$$

$$\frac{2ac}{a^2 + c^2} = \frac{3}{4}$$

$\therefore \sin 2\theta = \boxed{\dfrac{3}{4}}$.

Solution II

Key Word Trigonometric Identities, Law of Sines
From the diagram above, the Law of Sines could be used.

$$\frac{c}{\sin\theta} = \frac{a}{\sin(90+\theta)} = \frac{\frac{a+c}{2}}{\sin B} = \frac{a+c}{\sin\theta + \sin(90+\theta)}$$

In another words,

$$2\sin B = \sin\theta + \sin(90+\theta) = 2\sin\frac{\theta + (\theta+90)}{2}\cos\frac{\theta - (\theta+90)}{2}$$
$$= 4\sin\frac{B}{2}\cos\frac{B}{2}$$

Therefore,

$$4\sin\frac{B}{2}\cos\frac{B}{2} = 2\sin\frac{\theta + (\theta+90)}{2}\cos\frac{\theta - (\theta+90)}{2}$$
$$= 2\sin\frac{2\theta + 90}{2}\cos 45°$$
$$= \sqrt{2}\cos\frac{B}{2}$$
$$4\sin\frac{B}{2} = \sqrt{2}$$
$$\sin\frac{B}{2} = \frac{\sqrt{2}}{4}$$
$$\sqrt{\frac{1-\cos B}{2}} = \frac{\sqrt{2}}{4}$$
$$\frac{1-\cos B}{2} = \frac{1}{8}$$
$$\therefore \boxed{\cos B = \frac{3}{4}}$$
